

Topic 2D - The Properties of Bonds

Electronegativity

Quantitative measure of an element's ability to attract electron density in a chemical bond.

Pauling Scale

Based on experimentally measured bond strengths in homo- (A-A) and heteronuclear (A-B) diatomic molecules.

The covalent contribution to the A-B bond is the geometric mean of the dissociation energies (ΔE) of the purely covalent A-A and B-B bonds, *i.e.*, $\sqrt{E_{AA}E_{BB}}$. The "Excess Bond Energy" (Δ), which is taken to be a measure of the ionic contribution to the A-B bond, is then defined as:

$$\Delta = E_{AB} - \sqrt{E_{AA}E_{BB}}$$

where E is the bond dissociation energy in kJ/mol.

The difference in electronegativity (χ , in eV) between elements A and B is then given by:

$$|\chi_A - \chi_B| = 0.102 \Delta^{1/2} = 0.102 \sqrt{E_{AB} - (E_{AA}E_{BB})^{1/2}}$$

where the constant 0.102 converts kJ/mol into eV.

Since Pauling's method gives only differences in electronegativity, an absolute numerical scale is established by defining a value for the most electronegative element, *viz.*, fluorine, *i.e.*, $\chi_{\text{Fluorine}} = 4.0$

Mullikan Scale

Defined as being proportional to the average of the first ionization energy (IE_1) and the electron affinity (EA):

$$\chi \text{ (Mullikan)} \propto \frac{1}{2}(IE_1 + EA) = 0.187(IE_1 + EA) + 0.17$$

where the R.H.S. of the above equation converts Mullikan E.N. values (in eV) into dimensionless Pauling E.N. values.

The Pauling scale of electronegativity is much more widely utilized than the Mullikan scale.

Example for HCl

Bond Strengths:	H-H	424 kJ/mol
	Cl-Cl	230 “
	H-Cl	419 “

$$\Delta = E_{AB} - \sqrt{E_{AA} E_{BB}} = 419 - \sqrt{424 \times 230} = 312 \text{ kJ/mol}$$

$$|\chi_A - \chi_B| = 0.102 \Delta^{1/2} = 0.102 \sqrt{419 - (424 \times 230)^{1/2}} = 1.05$$

The “accepted” Pauling Electronegativities for H and Cl are

$$\chi_H = 2.20 \qquad \chi_{Cl} = 3.16$$

for which

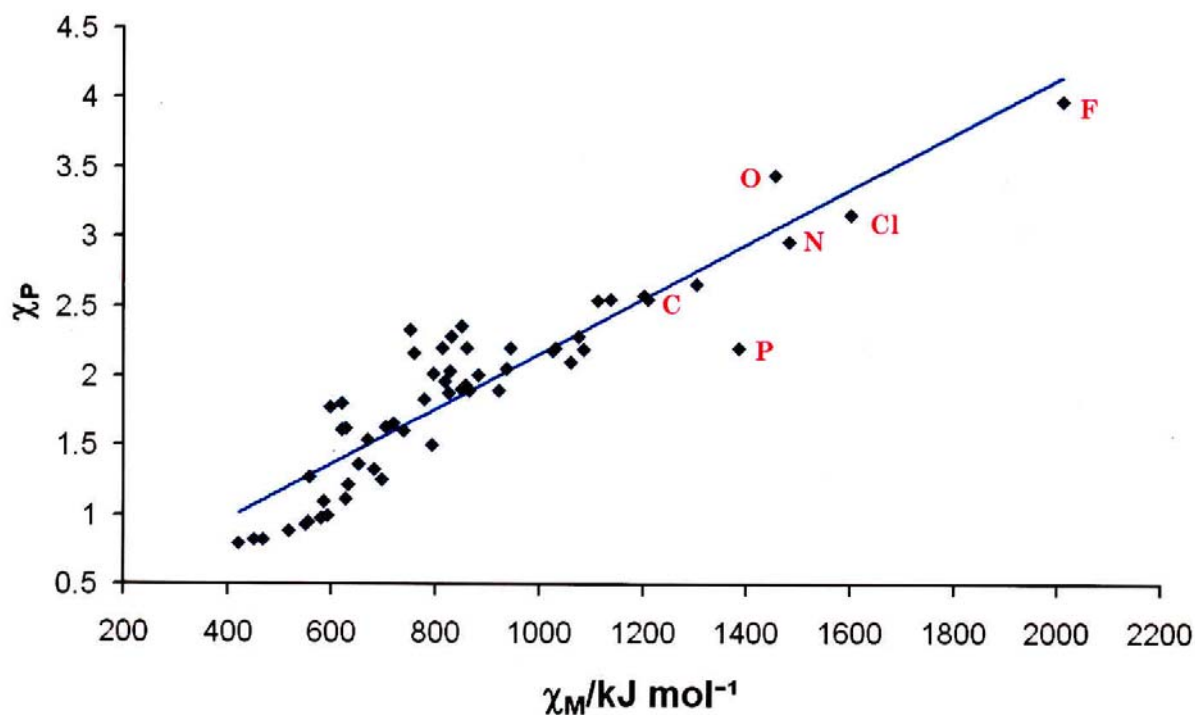

$$|\chi_A - \chi_B| = 3.16 - 2.20 = 0.96$$

which agrees reasonably well with the value of 1.05 calculated above for the specific case of HCl.

Pauling Electronegativities

Comparison of Pauling and Mullikan Electronegativity Scales:

Electronegativities of the Elements (Pauling scale)

→ Atomic radius decreases → Ionization energy increases → Electronegativity increases →

Difference in electronegativity ($\Delta\chi$) between two elements is indicative of the % ionic character (% I.C.) of a chemical bond between atoms of those elements. Approximate relationship between $\Delta\chi$ and % ionic character is given by:

$\Delta\chi$	% I.C.
0.0	0
1.0	20
1.5	40
1.75	50
2.0	60
2.5	80

The differing natures of chemical bonds are often loosely categorized according to their % I.C.:

% I.C.	Bond Type
0	Covalent
> 0, < 50	Polar Covalent
> 50	Ionic

Electron Density Progression from Covalent to Ionic Bonding

H-H (nonpolar covalent bond)

H-F (polar covalent bond)

NaI (ionic bond with some covalent character)

NaF (ionic bond)

Dipole Moment

A measure of the separation of charge in a molecule. Two unlike charges that are separated by a finite distance constitute an **electric dipole**.

A molecule that has such a charge separation possesses a **dipole moment**, μ :

$$\mu = qr$$

where q is the magnitude of the charge separation, and r is the distance between the charges $+q$ and $-q$. The dipole moment is a vector quantity, pointing toward the negative charge.

In SI units, μ is given in Coulomb-meters. The latter is an inconveniently large unit for molecules, so molecular dipole moments are conventionally given in **debyes (D)**, where

$$1 \text{ D} = 3.336 \times 10^{-30} \text{ C-m}$$

The Debye can also be defined as the dipole moment that arises from two charges $\pm e$ that are separated by 0.2082 \AA . Thus, if δ is the fractional unit charge on each atom in a diatomic molecule ($\delta = q/e$) and R is the equilibrium bond length, then

$$\mu(\text{D}) = \left[\frac{R(\text{\AA})}{0.2082 \text{ \AA}} \right] \delta$$

TABLE 3.7 Dipole Moments of Diatomic Molecules

Molecule	Bond Length (Å)	Dipole Moment (D)	Percent Ionic Character	
			(100δ)	$\Delta(\text{E.N.})$

NaF	1.931	8.156	88	3.1

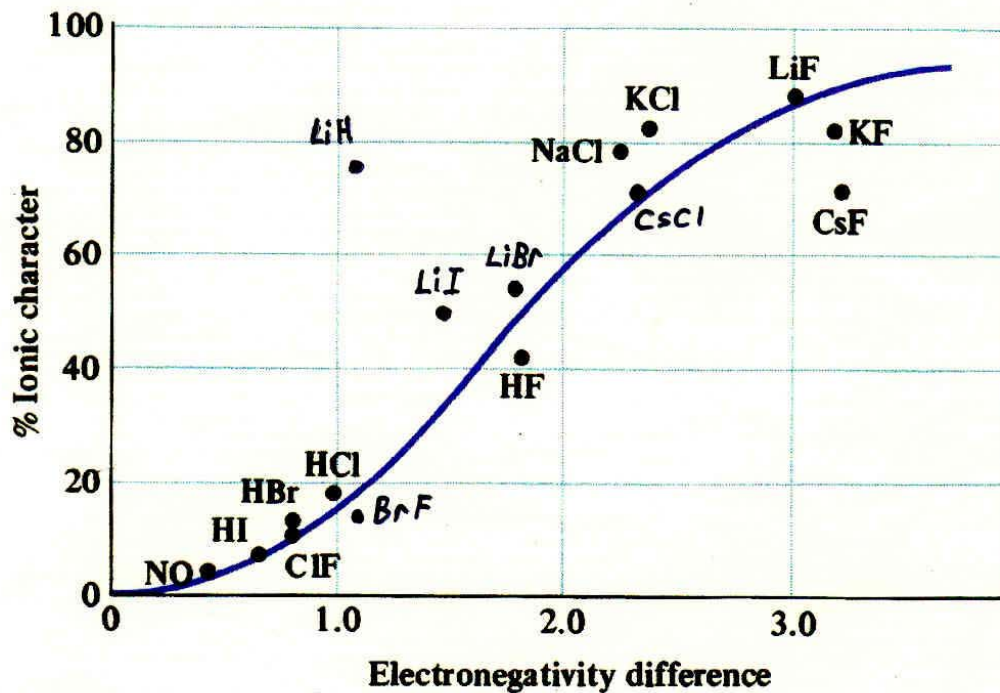

Figure 14-4

Two measures of ionic character for diatomic molecules are the electronegativity difference (from Fig. 14-1) and the percent ionic character 100δ (calculated from the observed dipole moment and bond length). The curve in this graph shows that the two correlate approximately but that there are many exceptions.
