Electronegativity Scales

Electric Dipole Moments

Lewis Structures;

Oxidation States;

Formal Charges

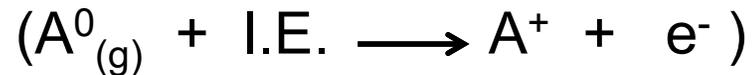

Trends in Atomic Properties

- **Size** (atomic, ionic, covalent, van der Waals radii)
- **Ionization Potential** ($A^0_{(g)} + \text{I.E.} \longrightarrow A^+ + e^-$)
- **Electron Affinity Energies** ($A^0_{(g)} + e^- \longrightarrow A^- + \text{E.A.E.}$)
- **Electronegativity:** Ability of an atom, within a molecule to attract electrons to itself.

Trends in Atomic Properties

- **Size** (atomic, ionic, covalent, van der Waals radii)

- **Ionization Potential energy**

- **Electron Affinity Energy** ($A^0_{(g)} + e^- \longrightarrow A^- + \text{E.A.E.}$)

- **Electronegativity:** Ability of an atom, within a molecule to attract electrons to itself.

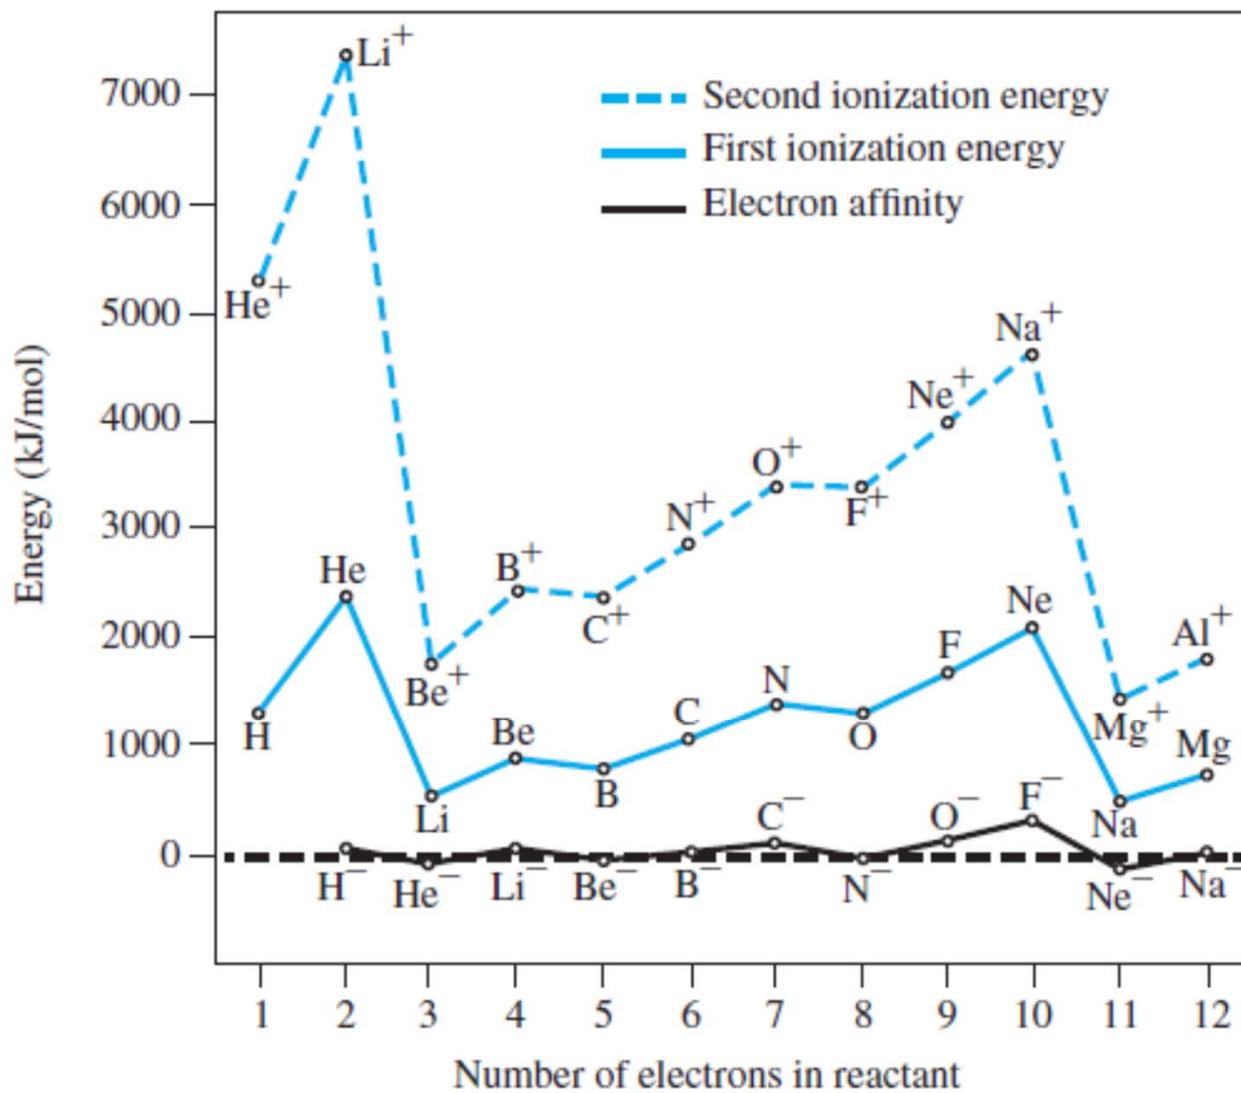

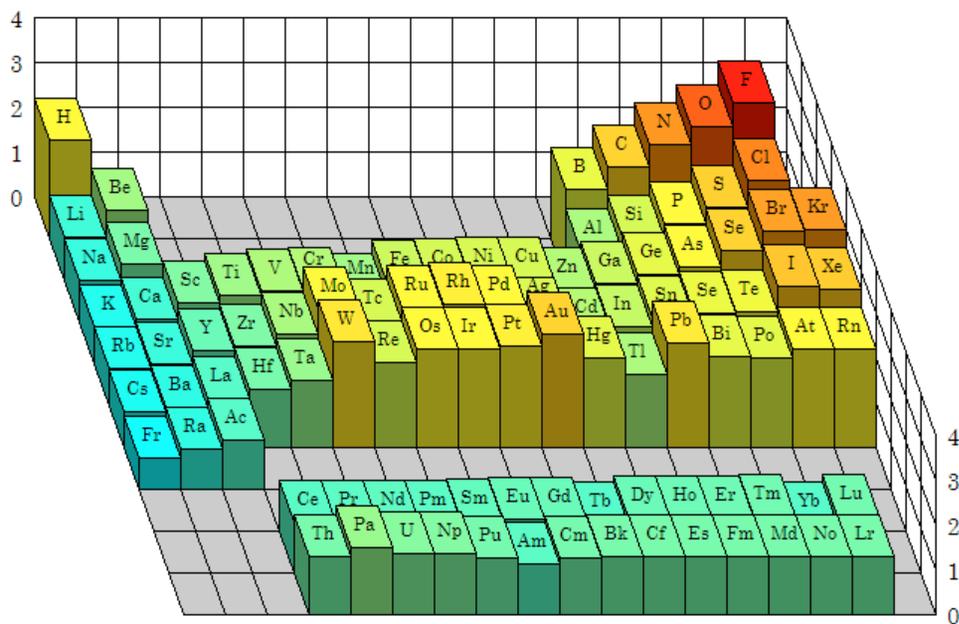

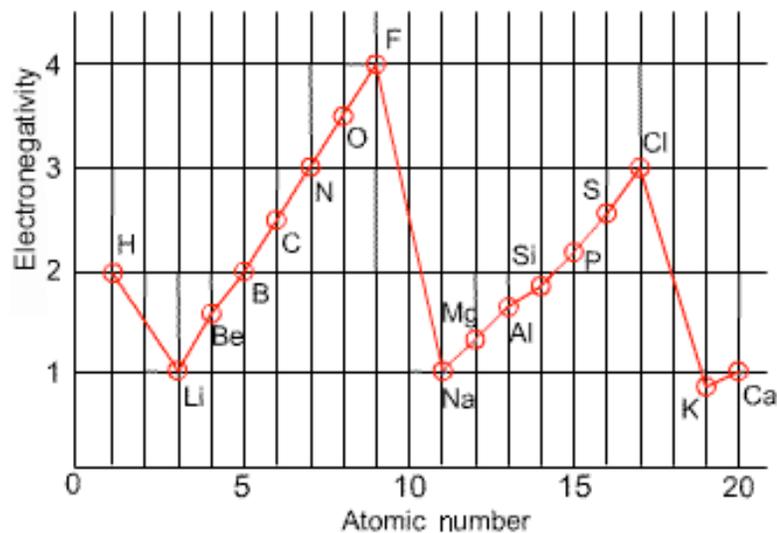

Table 1.6 First electron affinities of the main-group elements, $E_a/(\text{kJ mol}^{-1})^*$

H								He
72								-48
Li	Be	B	C	N	O	F		Ne
60	≤ 0	27	122	-8	141	328		-116
					-780			
Na	Mg	Al	Si	P	S	Cl		Ar
53	≤ 0	43	134	72	200	349		-96
					-492			
K	Ca	Ga	Ge	As	Se	Br		Kr
48	2	29	116	78	195	325		-96
Rb	Sr	In	Sn	Sb	Te	I		Xe
47	5	29	116	103	190	295		-77

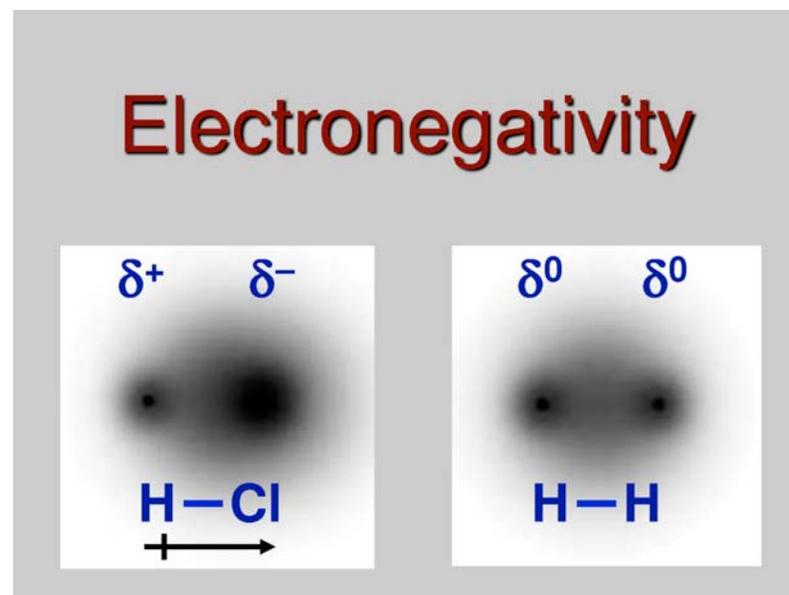

* The first values refer to the formation of the ion X^- from the neutral atom; the second value to the formation of X^{2-} from X^- .

BDE: 427

436 kJ/mol

Electronegativity-

- Pauling

$$|\chi_A - \chi_B| = 0.208 \sqrt{E_{A-B} - \frac{1}{2}(E_{A-A} + E_{B-B})}$$

arithmetic mean

$$|\chi_A - \chi_B| = 0.208 \sqrt{E_{A-B} - (E_{A-A} \cdot E_{B-B})^{1/2}}$$

geometric mean

- Mulliken

$$\chi_m = \frac{1}{2}(I + E_{ea})$$

Allred and Rochow Scale

This scale considers electronegativity as the force acting on electrons at a distance of the covalent radius.

- Rochow

$$\chi = 0.744 + \frac{0.359 Z_{\text{eff}}}{r_{\text{cov}}^2}$$

Z_{eff} = Effective nuclear charge

r_{cov} = Covalent radius of the atom in Angstroms.

Linus Pauling

BDE H_2 = 436 kJ/mol

BDE Cl_2 = 239

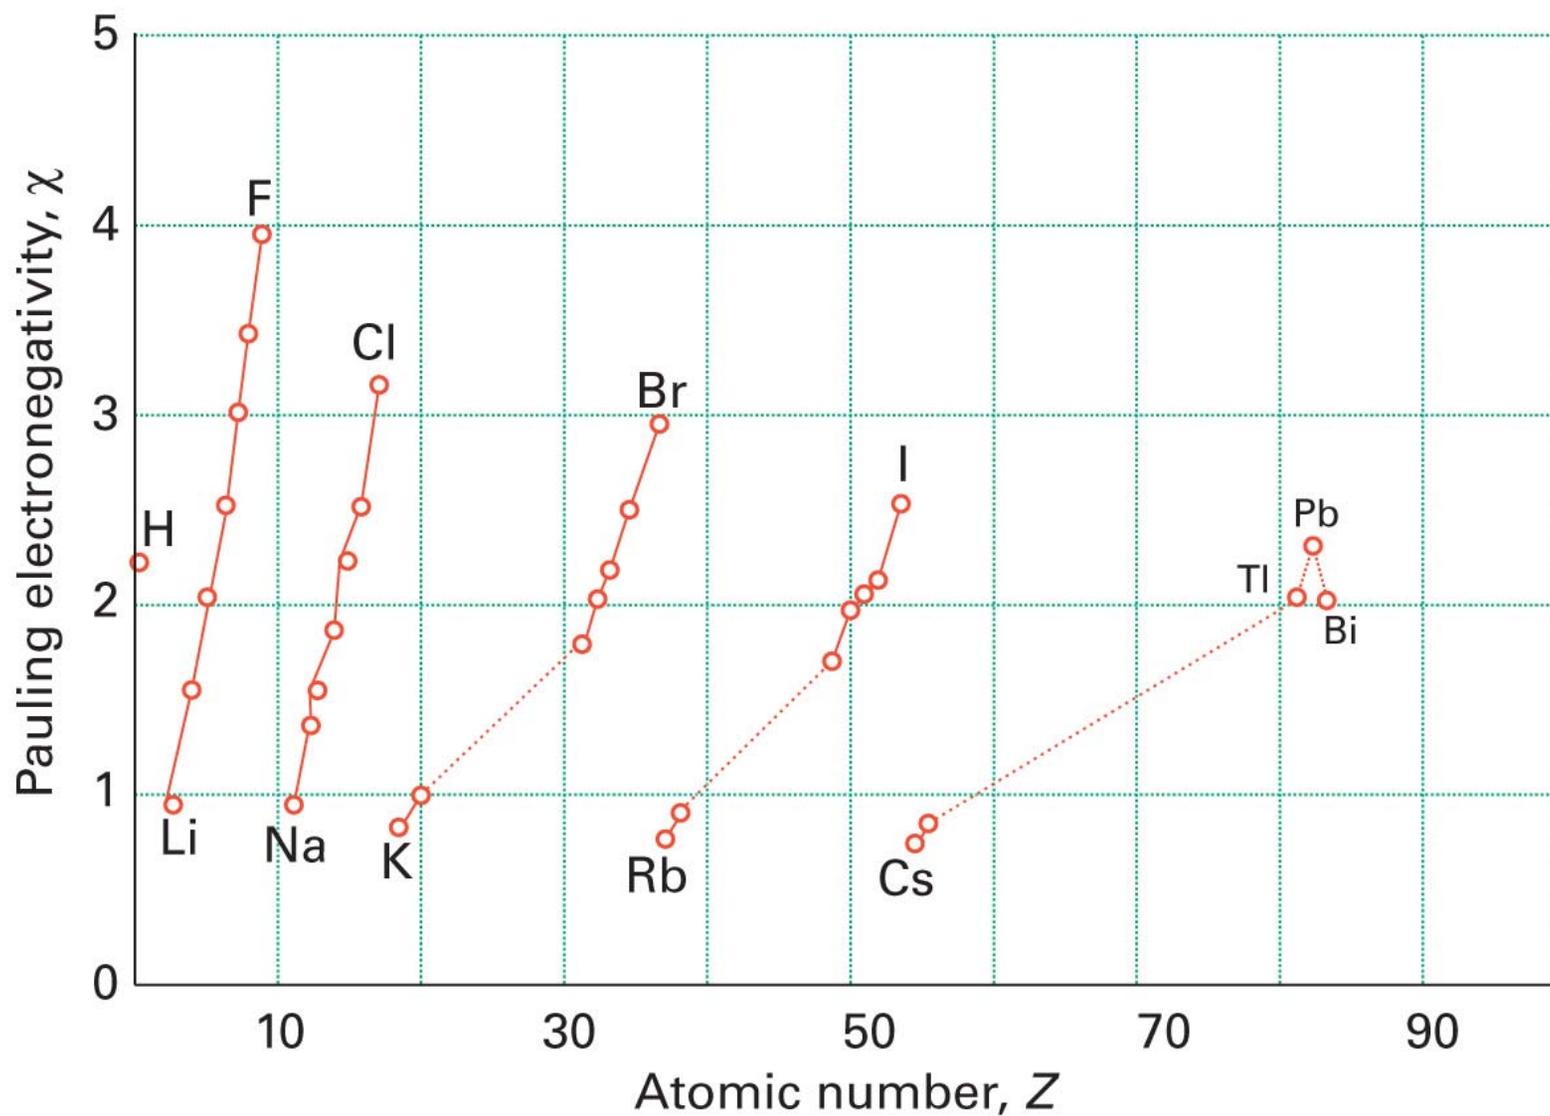

BDE HCl = 427

Pauling: If strictly covalent: BDE HCl should be average of H_2 and Cl_2

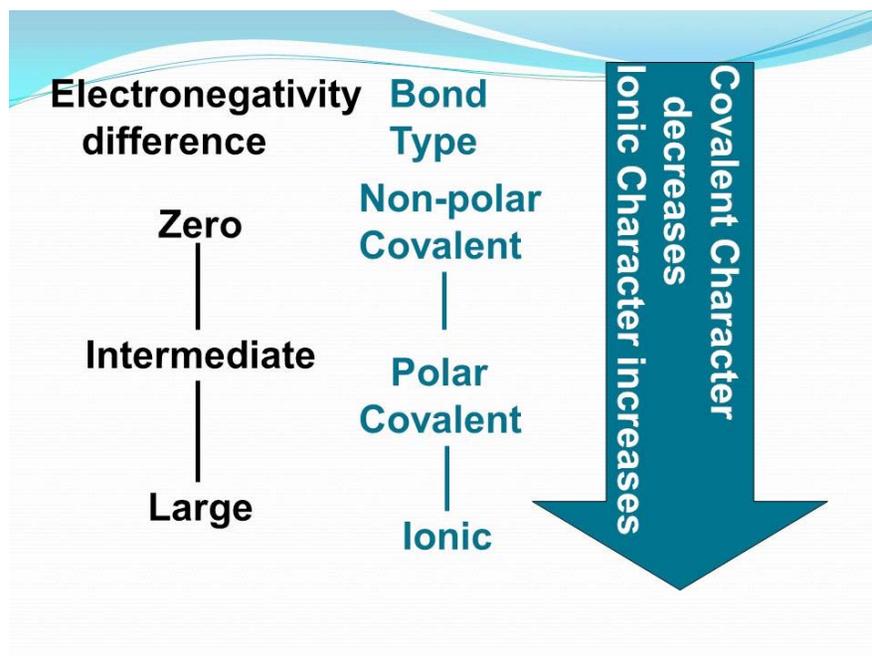

Which would be $\frac{1}{2} (436 + 239) = 338$ kJ/mol. The extra stability is
Due to electronegativity difference, and **electrostatic attraction**. That is, this
Bond is polar covalent.

Significance: Bond type

en= electronegativity

en > 1.7 = ionic bond

en < 1.7 = Polar covalent bond

**en = 0
is non-polar covalent bond**

Properties of Hydrogen Halides: polar covalent bonds, bond dipoles, electric dipole moments,

$$\mu = q \times r$$

Hydrogen Fluoride (HF)

m.p. -83.1°C, b.p. 19.9°C

pKa (aq) 3.17

r(H-F) = 0.92 Å; dipole moment = 1.8D

Hydrogen Chloride (HCl)

m.p. -114.2°C, b.p. -85.0 deg.C

pKa (aq) -7

r(H-Cl) = 1.28 Å; dipole moment = 1.1D

Hydrogen Bromide (HBr)

m.p. -86.8°C, b.p. -66.7°C

pKa (aq) -9

r(H-Br) = 1.41 Å; dipole moment = 0.8D

Hydrogen Iodide (HI)

m.p. -50.8°C, b.p. -35.35°C

pKa (aq) -10

r(H-I) = 1.60 Å; dipole moment = 0.4D

Why??? Electric dipole moment is the product of magnitude of charges and the distance of separation between the charges. Magnitude of charges will depend on difference in electronegativity of the atoms. Now in this case, F has highest electronegativity hence HF will have highest magnitude of charges. But, as we go down the group, the atomic radii increases, hence the distance of separation (bond length) will increase. So, we would expect the two factors to balance each other. Here, it seems the difference in electronegativity out weighs the distance (bond length) and that is why Dipole moment decreases,

Covalent bond types

- Polar molecules
 - Electrons are not *equally* shared
 - One part of molecule is more negative than the another part of the molecule
 - Molecule thus has negative and positive 'poles' like a battery
 - Hydrophilic ('water loving')
- Nonpolar molecules
 - Electrons are *equally* shared
 - No one part of molecule is distinctly negative or positive; no 'poles'
 - Hydrophobic 'water fearing'
