

Chapter 10: Bonding & Molecular Structure - Hybridization & Molecular Orbitals

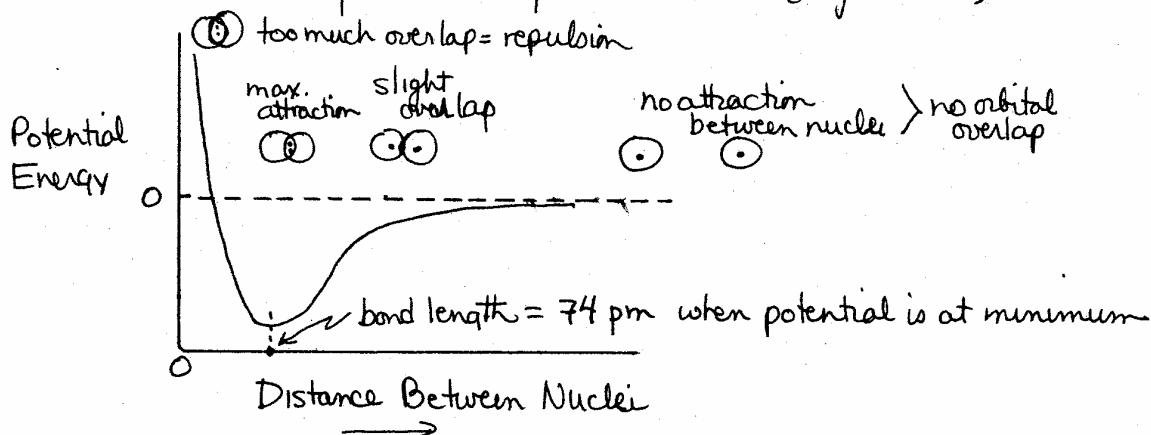

Chemical bonding in covalent compounds can be explained by

- (VB) (1) Valence Bond Theory - bonding results from overlap of atomic orbitals
- (MO) (2) Molecular Orbital Theory - a model of bonding in which pure atomic orbitals combine to produce molecular orbitals that are delocalized over 2 or more atoms.

VB Theory gives a good visual picture of molecular structure

MO Theory gives a quantitative picture of bonding. It is more complex and is the only theory that explains why O_2 is paramagnetic.

How does orbital overlap work to form bonds? (Figure 10-1)

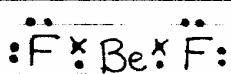

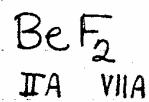

But - how can we have orbital overlap with our familiar s, p and d orbitals to get the shapes we know occur with VSEPR theory?
Geometries like trigonal planar? Tetrahedral? etc.

Linus Pauling proposed the theory of orbital hybridization. A new set of orbitals called hybrid orbitals can be created by mixing, s p + d orbitals to get new orbitals.

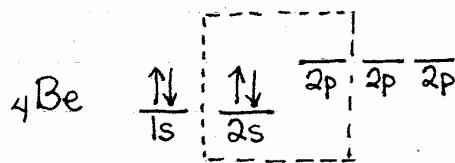

Let's look at the kind of hybridization that can occur:

Hybridization	Regions of high electron density around central atom	Electronic Geometry	
sp	2	linear	s + p orbitals $\xrightarrow{\text{hybridization}}$ 2 sp hybrid orbitals (mixing)
sp ²	3	trigonal planar	s + p + p orbitals $\xrightarrow{\text{hyb.}}$ 3 sp ² hybrid orbitals
sp ³	4	tetrahedral	s + p + p + p orbitals $\xrightarrow{\text{hyb.}}$ 4 sp ³ hybrid orbitals
sp ³ d	5	trigonal bipyramidal	s + p + p + p + d orbitals $\xrightarrow{\text{hyb.}}$ 5 sp ³ d hybrid orbitals
sp ³ d ²	6	octahedral	s + p + p + p + d + d orbitals $\xrightarrow{\text{hyb.}}$ 6 sp ³ d ² hybrid orbitals

Examples:

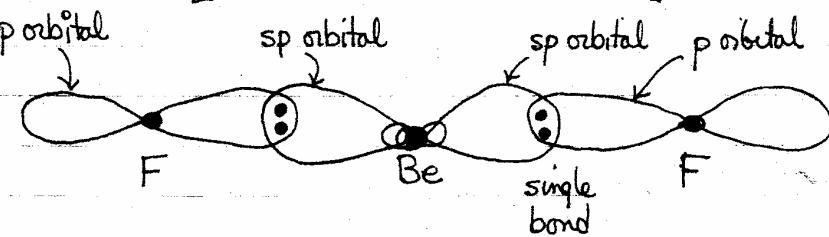

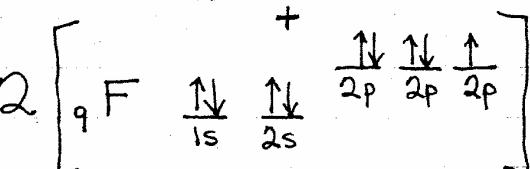

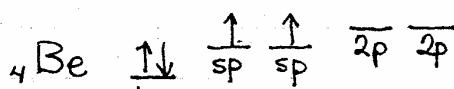

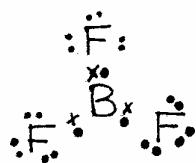

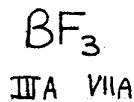

2 regions of hi electron density
linear
sp hybridization

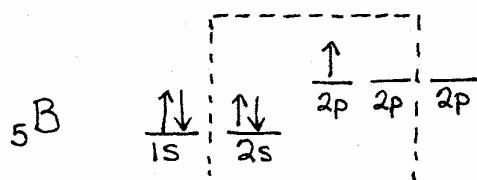

p sublevel has higher energy than s sublevel

↓ hybridization

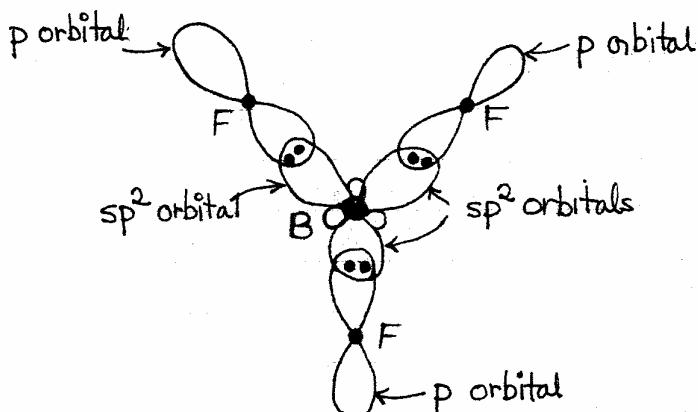

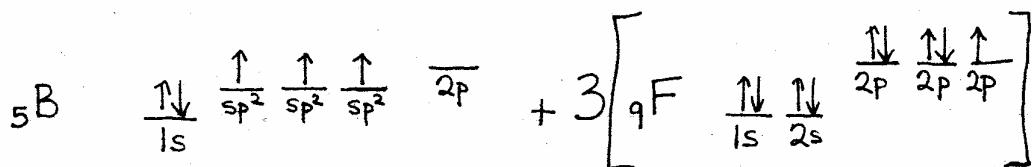

3 regions of high electron density
Electronic geometry is trigonal planar
 sp^2 hybridization

\Downarrow hybridization

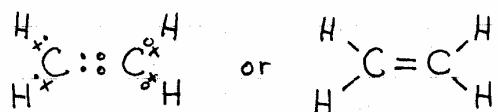

Up to now we have been concerned with ELECTRONIC geometry - referring to the arrangement of the valence shell electrons around the central atom.

The MOLECULAR geometry refers to the arrangement of atoms around the central atom - ie what the molecule or ion really looks like.

At the same time, will talk about the polarity of the molecule or ion: whether the species is POLAR or NONPOLAR. A species can contain polar bonds but be nonpolar, when the pulling on the electrons balances out. See Ch. 9.

Compounds Containing Double Bonds

Consider ethylene (ethene) C_2H_4

$$S = N - A$$

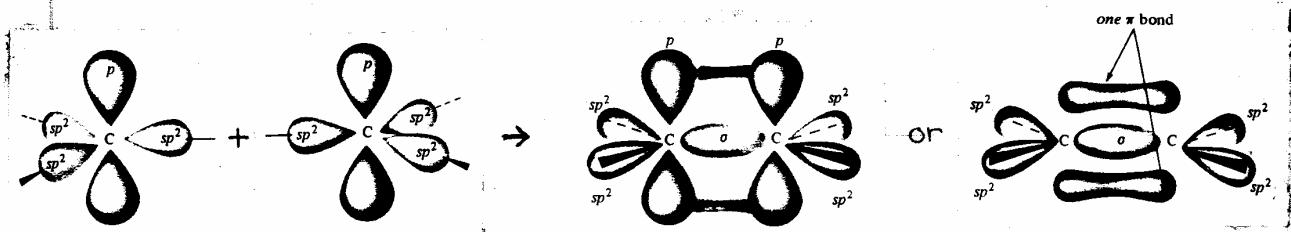

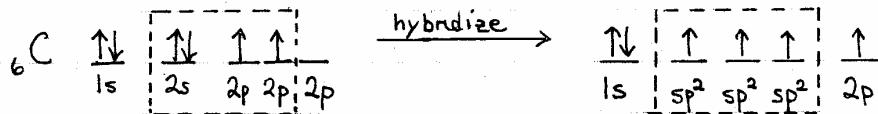

$$= [4 \times 2 (\text{for } H) + 2 \times 8 (\text{for } C)]$$

$$- (4 \times 1 (\text{for } H) + 2 \times 4 (\text{for } C))$$

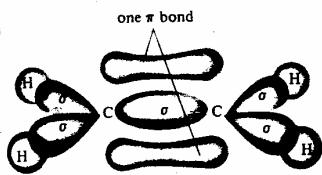

$$= 24 - 12 = 12 \text{ shared electrons}$$

both carbon atoms are sp^2 hybridized (have 3 regions of high electron density)
 each carbon is at the center of a trigonal plane
 the carbons are connected by a double bond

But what exactly is a double bond?

Therefore, for ethene :

∴ double bond is result of

1 σ bond and 1 π bond

∴ ethene has a total of 5 bonds
 1 π bond

Sigma (σ) bond : result of head-on (end-to-end) overlap
 there is free rotation around σ bond

Pi (π) bond : result of side-on overlap of p orbitals

there is NO free rotation around a π bond - the side-on overlap of p orbitals locks the molecule into place at that point

Compounds Containing Triple Bonds

Consider acetylene (ethyne) C_2H_2

$$S = N - A$$

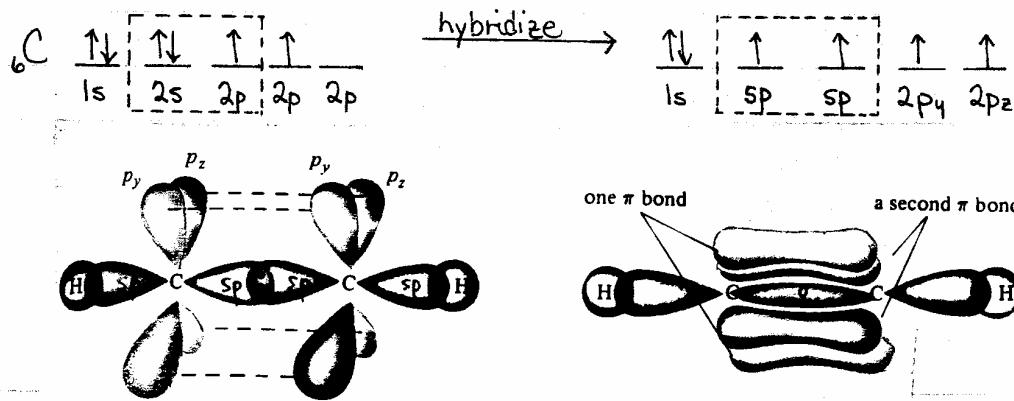

$$\begin{aligned} &= [2 \times 2(\text{fr H}) + 2 \times 8(\text{fr C})] \\ &\quad - (2 \times 1(\text{fr H}) + 2 \times 4(\text{fr C})) \\ &= 20 - 10 = 10 \end{aligned}$$

both C atoms are sp hybridized

the molecule is linear

the carbon atoms are connected by a triple bond.

But what is a triple bond?

∴ a triple bond is the result of 1 σ bond and 2 π bonds

∴ ethyne $H-C \equiv C-H$ contains 3 σ bonds and 2 π bonds.

Summary:

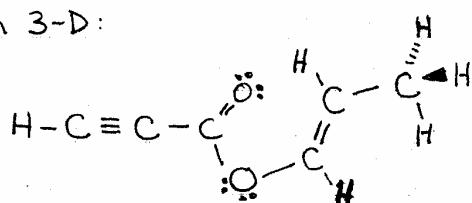

- (1) all single bonds are sigma (σ) bonds formed by the normal, head-on overlap of orbitals.
- (2) double bond : 1 σ bond, 1 π bond
- (3) triple bnd : 1 σ bond, 2 π bonds

Review of hybridization using organic compounds:

- (1) Know organic names & structures on sheet.
- (2) Recall that all organic compounds (C-containing compounds) obey the octet rule. Each carbon has 4 bonds around it since there are never any lone pairs of electrons on C.

Examples

		Atom	Hybridization	Bond Angle (ideal)
1. $\text{C}_2\text{H}_5\text{OH}$ (ethanol)	$\begin{array}{c} \text{H} \quad \text{H} \\ \quad \\ \text{H}-\text{C}^{\textcircled{1}}-\text{C}^{\textcircled{2}}-\ddot{\text{O}}^{\textcircled{3}}-\text{H} \\ \quad \\ \text{H} \quad \text{H} \end{array}$ S = N - A $= 36 - 20$ $= 16$	$\text{C}^{\textcircled{1}}$ $\text{C}^{\textcircled{2}}$ $\text{O}^{\textcircled{3}}$	sp^3 sp^3 sp^3	$109^\circ 28'$ $109^\circ 28'$ $109^\circ 28'$
	Lone pairs - 2 6 bonds - 8 π bonds - 0			
2. CH_3COOH (acetic acid)	$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \\ \quad \quad \\ \text{H}-\text{C}^{\textcircled{1}}-\text{C}^{\textcircled{2}}-\ddot{\text{O}}^{\textcircled{3}}-\text{H} \\ \quad \\ \text{H} \quad \text{H} \end{array}$ S = N - A $= 40 - 24$ $= 16$	$\text{C}^{\textcircled{1}}$ $\text{C}^{\textcircled{2}}$ $\text{O}^{\textcircled{3}}$ $\text{O}^{\textcircled{4}}$	sp^3 sp^2 sp^2 sp^3	$109^\circ 28'$ 120° 120° $109^\circ 28'$
	Lone pairs - 4 6 bonds - 7 π bonds - 1			
3.	$\begin{array}{c} \text{H} \quad \text{H} \quad \text{H} \\ \quad \quad \\ \text{H}-\text{C}^{\textcircled{1}} \equiv \text{C}^{\textcircled{2}}-\text{C}^{\textcircled{3}}-\ddot{\text{O}}^{\textcircled{4}}-\text{C}^{\textcircled{5}}=\text{C}^{\textcircled{6}}-\text{C}^{\textcircled{7}}-\text{C}^{\textcircled{8}}-\text{H} \\ \quad \quad \\ \text{H} \quad \text{H} \quad \text{H} \end{array}$ lone pairs - 4 O bonds - 13 π bonds - 4	$\text{C}^{\textcircled{1}}$ $\text{C}^{\textcircled{2}}$ $\text{C}^{\textcircled{3}}$ $\text{O}^{\textcircled{4}}$ $\text{O}^{\textcircled{5}}$ $\text{C}^{\textcircled{6}}$ $\text{C}^{\textcircled{7}}$ $\text{C}^{\textcircled{8}}$	sp sp sp^2 sp^2 sp^3 sp^2 sp^2 sp^3	180° 180° 120° 120° $109^\circ 28'$ 120° 120° $109^\circ 28'$
	In 3-D:			
	$\begin{array}{c} \text{H} \quad \text{H} \\ \diagdown \quad \diagup \\ \text{H}-\text{C} \equiv \text{C}-\text{C} \quad \text{C}-\text{C}-\text{H} \\ \diagup \quad \diagdown \\ \text{H} \quad \text{H} \end{array}$			

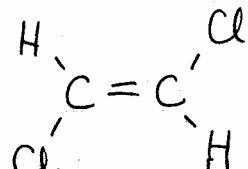

Cis-Trans Isomerism - a consequence of π bonding in double bonds

In a double bond, the π bond "locks" the molecule into place.
(There is free rotation around single bonds - sigma bonds)

Look at

vs

cis-1,2 dichloroethene

mp -80.5°C

bp 60.3°C

trans-1,2 dichloroethene

-50°C

47.5°C

These compounds are isomers because they have same chemical formula

but are different compounds, with different boiling & melting points.
