Topic 6J - Precipitation

Precipitation

Dissolution occurs when $Q_{sp} < K_{sp}$ Precipitation occurs when $Q_{sp} > K_{sp}$

Dissolving precipitates:

$$Fe(OH)_3$$
 (s) = Fe^{3+} (aq) + 3 OH^- (aq)

Addition of acid (H₃O⁺) causes a <u>decrease</u> in [OH⁻], thus causing more Fe(OH)₃ to dissolve.

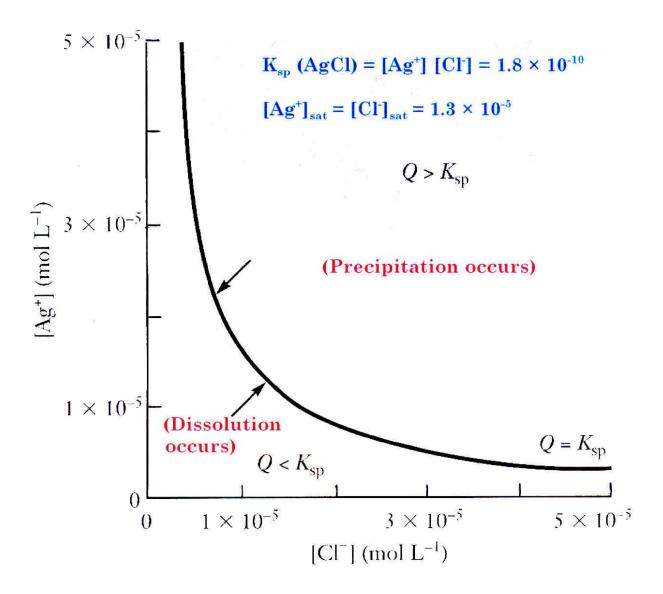

$$CaCO_3(s) = Ca^{2+}(aq) + CO_3^{2-}(aq)$$

Addition of acid causes a <u>decrease</u> in [CO₃²-], due to evolution of CO₂, thus driving the equilibrium to the right and causing more CaCO₃ to dissolve:

$$CO_3^{2-}(aq) + 2 H_3O^+(aq) \rightarrow CO_2(g) + 3 H_2O(l)$$

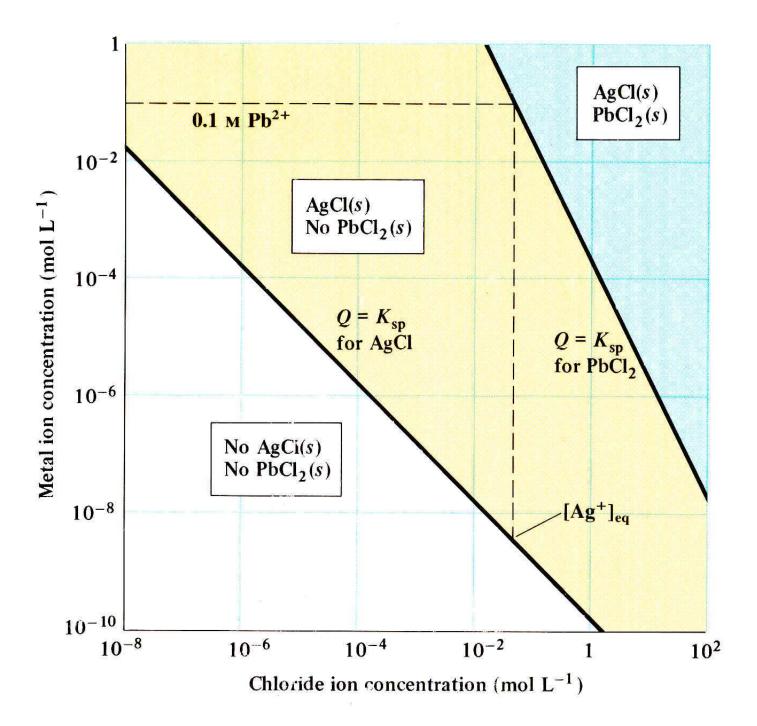

(This process is responsible for the effect of acid rain in causing the deterioration of limestone structures.)

chloride is in contact with a solution containing $Ag^+(aq)$ and $Cl^-(aq)$ ions. If a solubility equilibrium exists, then the product Q of the concentrations of the ions $[Ag^-] \times [Cl^-]$ is a constant, $K_{\rm sp}$ (curved line). When Q exceeds $K_{\rm sp}$, solid silver chloride tends to precipitate until equilibrium is attained. When Q is less than $K_{\rm sp}$, additional solid tends to dissolve. If no solid is present, Q remains less than $K_{\rm sp}$.
